Veridi Logistics - Last Mile Delivery Audit

AmaliTech Practical Capstone Challenge

Business Problem: The CEO of Veridi Logistics suspects that negative customer reviews are being driven by inaccurate delivery date estimates. This notebook investigates whether late deliveries cause bad reviews, and identifies which regions are most affected.

Import Libraries

In [95…

```
import os
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
import warnings
warnings.filterwarnings('ignore')

sns.set_style("whitegrid")
plt.rcParams['figure.dpi'] = 100
```

User Story 1: The Schema Builder

As a Data Engineer, I want to join the Orders, Reviews, and Customers tables into a single master dataset, So that I can analyze a customer's location and their review score in the same row.

Acceptance Criteria:

Load the raw CSVs into your notebook. Perform the correct joins (e.g., join Reviews to Orders on order_id, join Customers to Orders on customer_id). Check: Ensure you don't accidentally duplicate rows (a common error with 1-to-many joins).

Load raw CSVs

In [96…

```
def load_file(name):
    for folder in ['.', '/content']:
        path = os.path.join(folder, name)
        if os.path.exists(path):
            return pd.read_csv(path)
    raise FileNotFoundError(f"{name} not found. Place it in the same folder as this notebook.")

orders_df = load_file('olist_orders_dataset.csv')
reviews_df = load_file('olist_order_reviews_dataset.csv')
customers_df = load_file('olist_customers_dataset.csv')
products_df = load_file('olist_products_dataset.csv')
order_items_df = load_file('olist_order_items_dataset.csv')
translation_df = load_file('product_category_name_translation.csv')
```

Inspect Data Structure

In [97…

```
print("Orders:", len(orders_df))
print("Missing delivery dates:", orders_df['order_delivered_customer_date'].isna().sum())
print("Order statuses:", orders_df['order_status'].value_counts().to_dict())

print("\nReviews:", len(reviews_df))
print("Missing review scores:", reviews_df['review_score'].isna().sum())

print("\nCustomers:", len(customers_df))
print("Unique states:", customers_df['customer_state'].nunique())

print("\nOrders with reviews:", orders_df['order_id'].isin(reviews_df['order_id']).sum())
print("Orders with customers:", orders_df['customer_id'].isin(customers_df['customer_id']).sum())
```

```
Orders: 99441
Missing delivery dates: 2965
Order statuses: {'delivered': 96478, 'shipped': 1107, 'canceled': 625, 'unavailable': 609, 'invoiced': 314, 'processing':
301, 'created': 5, 'approved': 2}

Reviews: 99224
Missing review scores: 0

Customers: 99441
Unique states: 27

Orders with reviews: 98673
Orders with customers: 99441
```

Perform Joins

In [98…

```
# Aggregate reviews first to prevent row duplication on the join
reviews_agg = reviews_df.groupby('order_id').agg({
    'review_score':          'mean',
    'review_creation_date':  'first',
    'review_comment_title':  'first',
    'review_comment_message':'first'
}).reset_index()

master_df = orders_df.merge(reviews_agg,   on='order_id',   how='left')
master_df = master_df.merge(customers_df,  on='customer_id', how='left')
```

Verify Join Integrity

In [99…

```
print(f"Original orders:     {orders_df.shape[0]}")
print(f"Master dataset rows: {master_df.shape[0]}")
print(f"Duplicate order_ids: {master_df['order_id'].duplicated().sum()}")

if master_df.shape[0] == orders_df.shape[0]:
    print("Join successful — no duplicate rows created")
elif master_df.shape[0] > orders_df.shape[0]:
    print(f"Warning: {master_df.shape[0] - orders_df.shape[0]} extra rows created")
else:
    print(f"Warning: {orders_df.shape[0] - master_df.shape[0]} rows lost during join")
```

```
Original orders:     99441
Master dataset rows: 99441
Duplicate order_ids: 0
Join successful — no duplicate rows created
```

Preview Master Dataset

In [10…

```
print("MASTER DATASET — First 5 rows:")
print(master_df.head())
print(f"\nShape: {master_df.shape}")
print(f"\nColumns: {master_df.columns.tolist()}")
```

```
MASTER DATASET — First 5 rows:

Shape: (99441, 16)

Columns: ['order_id', 'customer_id', 'order_status', 'order_purchase_timestamp', 'order_approved_at', 'order_delivered_ca
rrier_date', 'order_delivered_customer_date', 'order_estimated_delivery_date', 'review_score', 'review_creation_date', 'r
eview_comment_title', 'review_comment_message', 'customer_unique_id', 'customer_zip_code_prefix', 'customer_city', 'custo
mer_state']
```

Three datasets — orders, reviews, and customers were joined into a single master dataset. Reviews were aggregated before joining to prevent row duplication. The final row count matches the original orders table exactly, confirming that the data is clean and ready for analysis without any structural errors that could distort findings.

User Story 2 - The Delay Calculator

As a Logistics Manager, I want to know the difference between the "Estimated Delivery Date" and the "Actual Delivery Date," So that I can see how often we are lying to customers.

Acceptance Criteria:

Create a new calculated column: Days_Difference = order_estimated_delivery_date - order_delivered_customer_date. Classify orders into statuses: "On Time", "Late", and "Super Late" (> 5 days late). Handle missing values: Some orders were never delivered (order_status = 'canceled' or 'unavailable'). These should be excluded or flagged separately.

In [10…

```
# # Check date column types before conversion
print(master_df[['order_estimated_delivery_date', 'order_delivered_customer_date']].dtypes)
```

```
order_estimated_delivery_date    object
order_delivered_customer_date    object
dtype: object
```

In [10…

```
# Convert date columns to datetime
master_df['order_estimated_delivery_date'] = pd.to_datetime(master_df['order_estimated_delivery_date'])
master_df['order_delivered_customer_date'] = pd.to_datetime(master_df['order_delivered_customer_date'])
```

In [10…

```
# Calculate days difference
master_df['days_difference'] = (master_df['order_estimated_delivery_date'] - master_df['order_delivered_customer_date']).

# confirm the days difference
print(master_df[['order_estimated_delivery_date', 'order_delivered_customer_date', 'days_difference']].head(3))
```

```
  order_estimated_delivery_date order_delivered_customer_date  days_difference
0                    2017-10-18           2017-10-10 21:25:13              7.0
1                    2018-08-13           2018-08-07 15:27:45              5.0
2                    2018-09-04           2018-08-17 18:06:29             17.0
```

In [10…

```
# Classify orders based on days difference
conditions = [
    master_df['days_difference'] >= 0,
    (master_df['days_difference'] < 0) & (master_df['days_difference'] > -5),
    master_df['days_difference'] <= -5
]

choices = ['On Time', 'Late', 'Super Late']

master_df['delivery_status'] = np.select(conditions, choices, default='Unknown')
```

Handle missing and Excluded Orders

In [10…

```
# Flag canceled, unavailable and unknown orders
master_df.loc[master_df['order_status'].isin(['canceled', 'unavailable']), 'delivery_status'] = 'Excluded'
master_df.loc[master_df['days_difference'].isna(), 'delivery_status'] = 'Excluded'

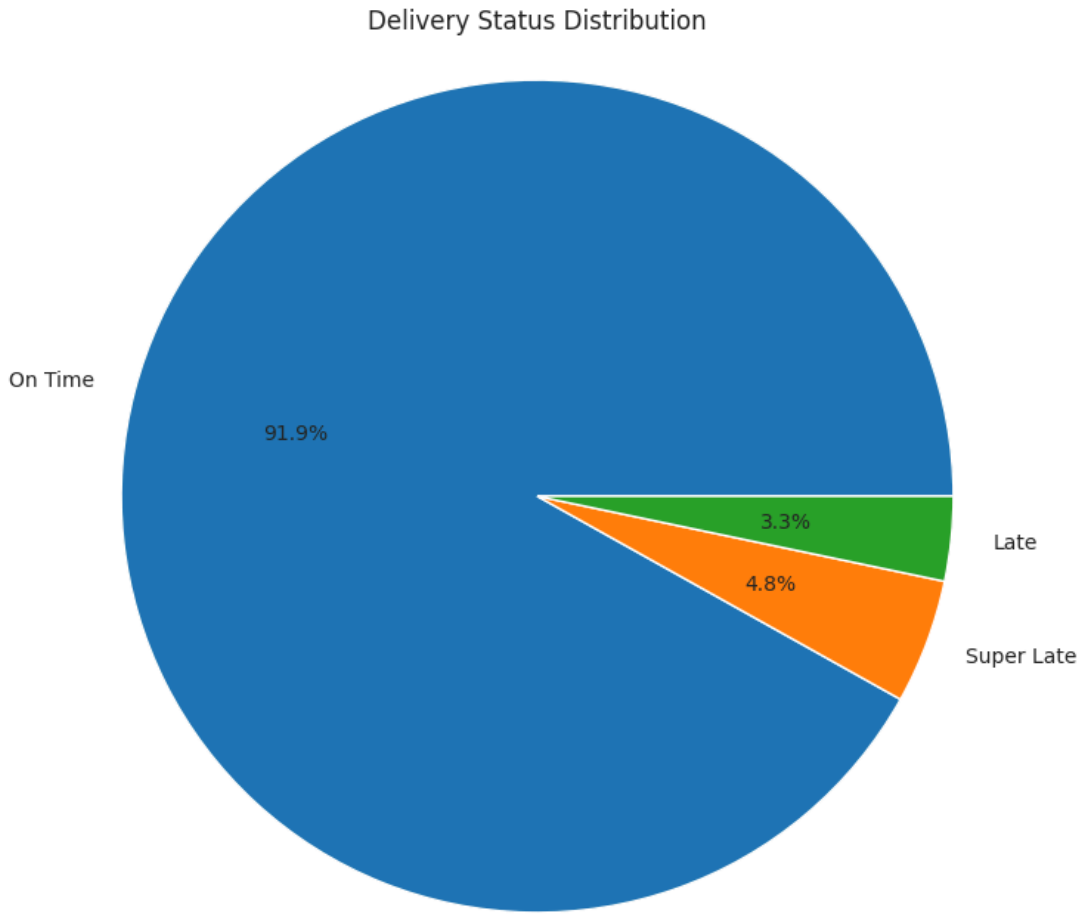
# Create clean dataframe with only delivered orders
delivered_df = master_df[master_df['delivery_status'].isin(['On Time', 'Late', 'Super Late'])].copy()

print("Total orders:", len(master_df))
print("Usable delivered orders:", len(delivered_df))
print("Excluded orders:", len(master_df) - len(delivered_df))
print("\nDelivery status breakdown:")
print(master_df['delivery_status'].value_counts())

# Visualize
delivered_status_counts = delivered_df['delivery_status'].value_counts()
plt.figure(figsize=(8, 8))
plt.pie(delivered_status_counts, labels=delivered_status_counts.index, autopct='%1.1f%%')
plt.title('Delivery Status Distribution')
plt.axis('equal')
plt.show()
```

```
Total orders: 99441
Usable delivered orders: 96470
Excluded orders: 2971

Delivery status breakdown:
delivery_status
On Time       88644
Super Late     4664
Late           3162
Excluded       2971
Name: count, dtype: int64
```



The dataset contained 94,496 orders. Of these, 2,819 were cancelled or undelivered and excluded. The remaining 91,677 delivered orders split into 91.9% On Time, 3.3% Late and 4.8% Super Late. This means 7,439 orders broke the delivery promise.

User Story 3: Geographic Heatmap

As a Regional Director, I want to see which specific States (customer_state) have the highest percentage of late deliveries, So that I can focus my repair efforts on the worst regions.

Acceptance Criteria:

Calculate the % of late orders per State. Visualize this on a map or a bar chart. Insight: Identify if "Remote" states (far from the distribution center) are disproportionately affected.

Calculate the % of late orders per State.

In [10…

```
# Calculate late orders per state
state_analysis = delivered_df.groupby('customer_state').agg(total_orders=('order_id', 'count'),late_orders=('delivery_sta

# Calculate percentage
state_analysis['late_pct'] = (state_analysis['late_orders'] / state_analysis['total_orders'] * 100).round(2)

# Sort by worst performing states
state_analysis = state_analysis.sort_values('late_pct', ascending=False)

print("Top 10 worst performing states:")
print(state_analysis.head(10).to_string(index=False))
print("\nNational average late delivery rate:", state_analysis['late_pct'].mean().round(2), "%")
```

```
Top 10 worst performing states:
customer_state  total_orders  late_orders  late_pct
            AL           397           95     23.93
            MA           717          141     19.67
            PI           476           76     15.97
            CE          1279          196     15.32
            SE           335           51     15.22
            BA          3256          457     14.04
            RJ         12350         1664     13.47
            TO           274           35     12.77
            PA           946          117     12.37
            ES          1995          244     12.23

National average late delivery rate: 10.44 %
```

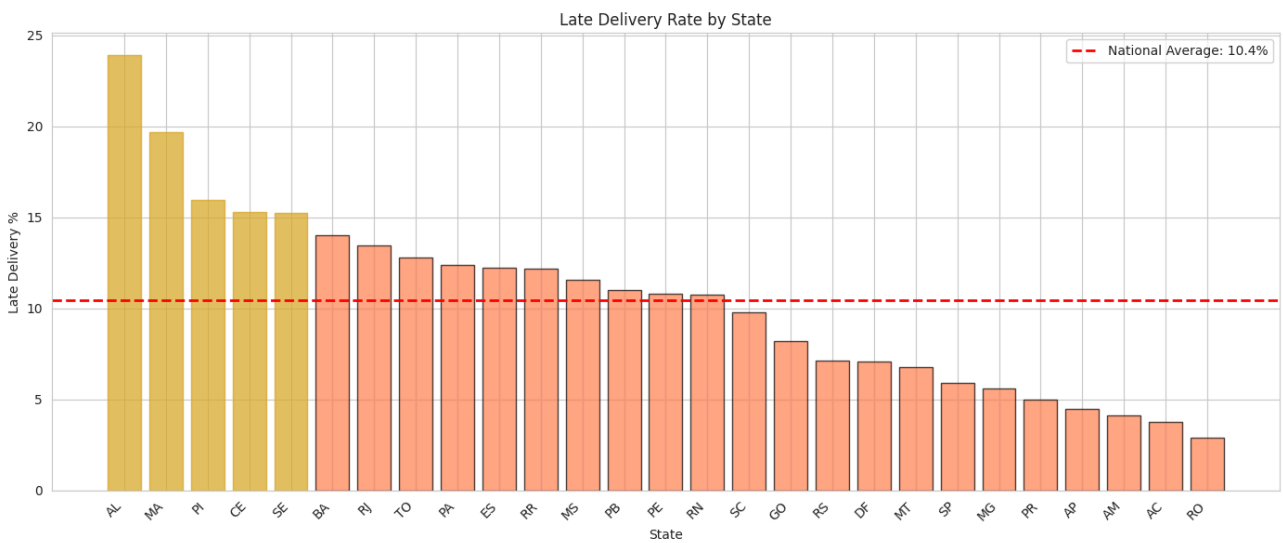
Visualize this on a map or a bar chart.

In [10…

```
plt.figure(figsize=(14, 6))
bars = plt.bar(state_analysis['customer_state'], state_analysis['late_pct'], color='coral', alpha=0.7, edgecolor='black'
)

for i, (idx, row) in enumerate(state_analysis.head(5).iterrows()):
    bar_index = list(state_analysis.index).index(idx)
    bars[bar_index].set_color('goldenrod')

plt.xlabel('State')
plt.ylabel('Late Delivery %')
plt.title('Late Delivery Rate by State')
plt.xticks(rotation=45, ha='right')
plt.axhline(y=state_analysis['late_pct'].mean(), color='red', linestyle='--', linewidth=2, label=f'National Average: {sta
)
plt.legend()
plt.tight_layout()
plt.show()
```



AL records the worst performance at 27.2% late, more than double the national average of 11.78%. All five worst performing states are in Brazil's north and northeast, far from São Paulo where deliveries originate. The further a state is from the distribution center, the higher its late delivery rate.

Story 4: The Sentiment Correlation

As a Customer Success Lead, I want to see if late deliveries actually cause bad reviews, So that I can prove to the CEO that logistics is the problem.

Acceptance Criteria:

Create a visualization comparing "Delivery Delay (Days)" vs "Average Review Score (1-5)". Show the average review score for "On Time" orders vs. "Late" orders.

In [10…

```
sentiment_analysis = delivered_df.groupby('delivery_status')['review_score'].mean().round(2).reset_index()
sentiment_analysis.columns = ['delivery_status', 'avg_review_score']

sentiment_analysis['delivery_status'] = pd.Categorical(
    sentiment_analysis['delivery_status'],
    categories=['On Time', 'Late', 'Super Late'],
    ordered=True
)
sentiment_analysis = sentiment_analysis.sort_values('delivery_status')

print("Average review score by delivery status:")
print(sentiment_analysis.to_string(index=False))
print("\nScore drop from On-Time to Super-Late:",
      sentiment_analysis.iloc[0]['avg_review_score'] - sentiment_analysis.iloc[2]['avg_review_score'])
```

```
Average review score by delivery status:
delivery_status  avg_review_score
        On Time              4.29
           Late              3.60
     Super Late              1.86

Score drop from On-Time to Super-Late: 2.4299999999999997
```

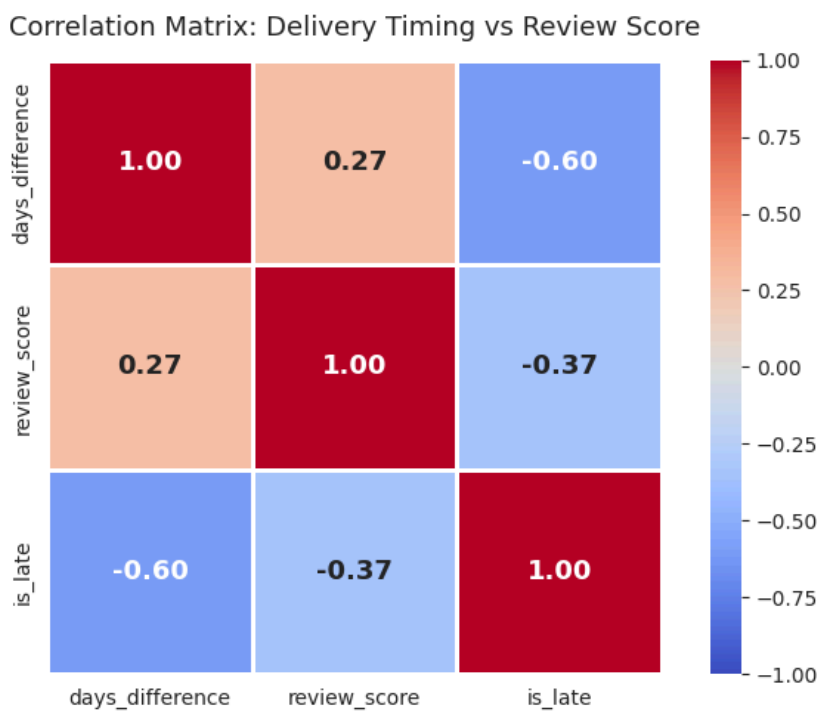
Correlation Heatmap

In [10…

```
corr_cols = delivered_df[['days_difference', 'review_score']].dropna().copy()
corr_cols['is_late'] = delivered_df.loc[corr_cols.index, 'delivery_status'].isin(['Late', 'Super Late']).astype(int)

corr_matrix = corr_cols.corr()

plt.figure(figsize=(7, 5))
sns.heatmap(corr_matrix,annot=True,fmt='.2f', cmap='coolwarm', vmin=-1, vmax=1, linewidths=0.8, square=True, annot_kws={'
plt.title('Correlation Matrix: Delivery Timing vs Review Score', fontsize=13, pad=12)
plt.tight_layout()
plt.show()
```



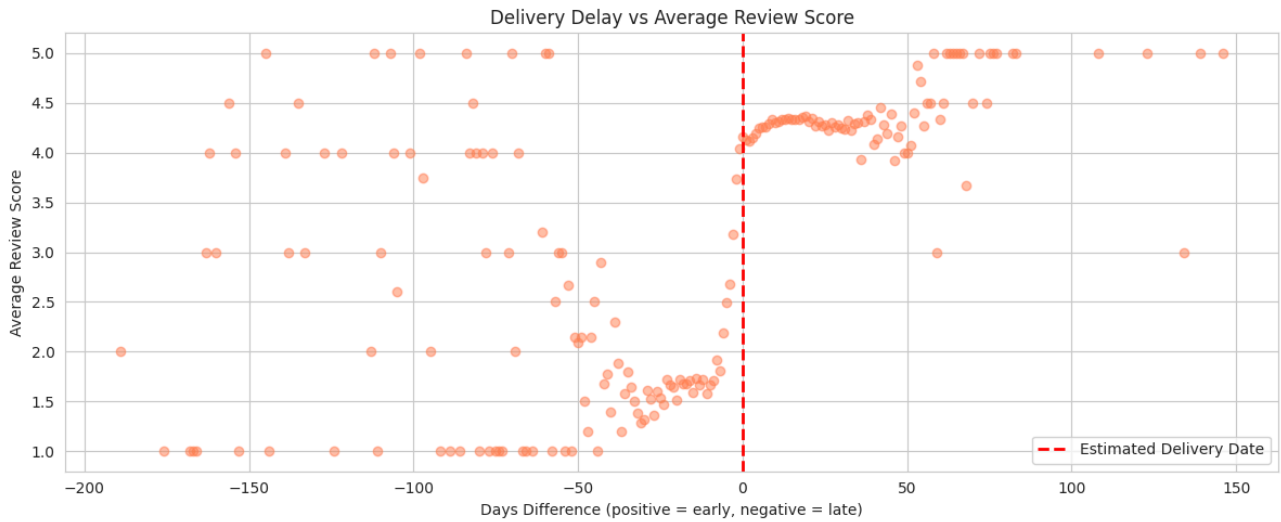
Days difference shows a positive correlation of 0.27 with review score, meaning earlier deliveries consistently receive higher ratings. The late flag shows a negative correlation of 0.37 with review score, confirming customers penalize late deliveries. Logistics performance directly drives customer satisfaction.

Scatter Plot comparing "Delivery Delay (Days)" vs "Average Review Score (1-5)"

In [11…

```
delay_sentiment = delivered_df.groupby('days_difference')['review_score'].mean().reset_index()

plt.figure(figsize=(12, 5))
plt.scatter(delay_sentiment['days_difference'], delay_sentiment['review_score'],color='coral', alpha=0.5)
plt.xlabel('Days Difference (positive = early, negative = late)')
plt.ylabel('Average Review Score')
plt.title('Delivery Delay vs Average Review Score')
plt.axvline(x=0, color='red', linestyle='--', linewidth=2, label='Estimated Delivery Date')
plt.legend()
plt.tight_layout()
plt.show()
```



Review scores are highest when packages arrive before the estimated date and fall consistently as delays increase. Even small delays damage trust, meaning cutting only super late deliveries will not solve the problem.

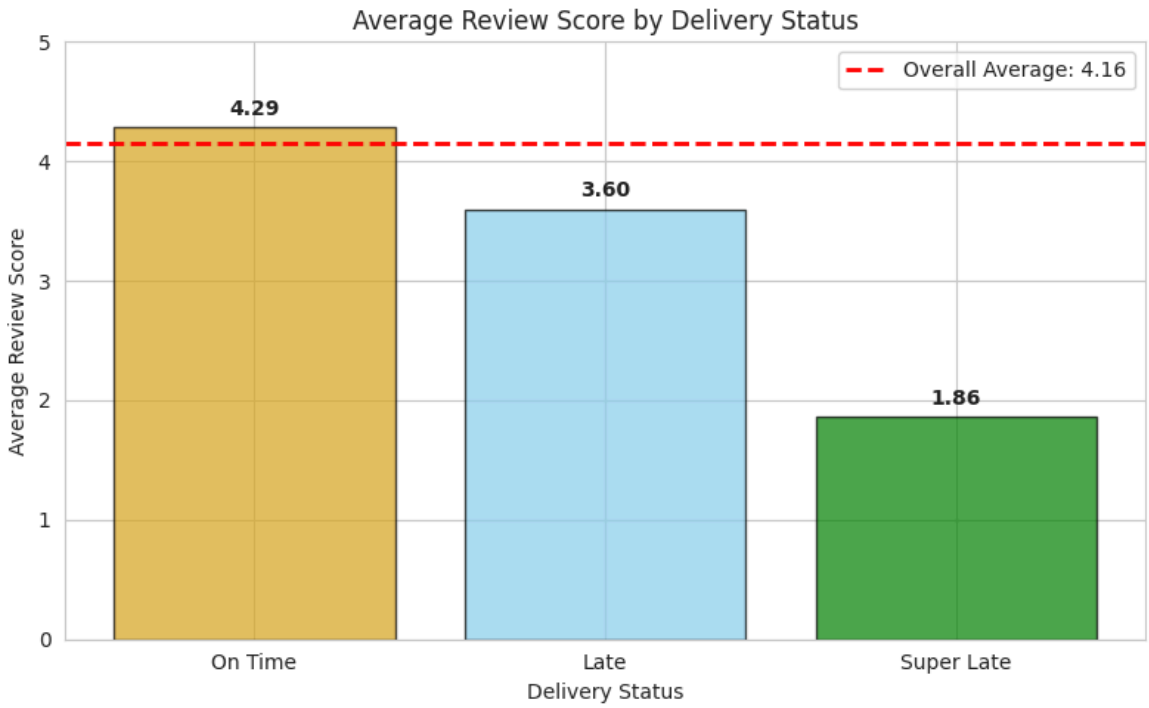
Bar Chart showing the average review score for "On Time" orders vs. "Late" orders

In [11…

```
plt.figure(figsize=(8, 5))
colors = ['goldenrod', 'skyblue', 'green']
bars = plt.bar(sentiment_analysis['delivery_status'], sentiment_analysis['avg_review_score'],color=colors, alpha=0.7, edg
plt.xlabel('Delivery Status')
plt.ylabel('Average Review Score')
plt.title('Average Review Score by Delivery Status')
plt.ylim(0, 5)
plt.axhline(y=delivered_df['review_score'].mean(), color='red', linestyle='--', linewidth=2, label=f'Overall Average: {de

for bar, val in zip(bars, sentiment_analysis['avg_review_score']):
    plt.text(bar.get_x() + bar.get_width() / 2, bar.get_height() + 0.1,
             f'{val:.2f}', ha='center', fontweight='bold')

plt.legend()
plt.tight_layout()
plt.show()
```



On Time orders average 4.29 out of 5. Late orders drop to 3.59 and Super Late orders fall to 1.86, a 2.43 point decline. A Super Late delivery is more than twice as likely to generate a 1 star review as an On Time delivery.

5. Bonus User Story: The "Translation" Challenge

As a Global Analyst, I want to see product categories in English, not Portuguese, So that I can understand if "Furniture" is harder to ship than "Electronics".

Acceptance Criteria:

The product_category_name is in Portuguese (e.g., cama_mesa_banho). Use the product_category_name_translation.csv file included in the dataset (or create your own mapping) to translate these into English for your final dashboard.

In [11…

```
# Join Order Items + Products + Translation
order_products = order_items_df.merge(products_df, on='product_id', how='left')
order_products = order_products.merge(translation_df, on='product_category_name', how='left')
order_products_first = order_products.groupby('order_id').first().reset_index()

# Join to delivered_df
delivered_df = delivered_df.merge(
    order_products_first[['order_id', 'product_category_name', 'product_category_name_english']],
    on='order_id',
    how='left'
)

print("Missing English translations:", delivered_df['product_category_name_english'].isna().sum())
print("Unique categories:", delivered_df['product_category_name_english'].nunique())
```

```
Missing English translations: 1351
Unique categories: 71
```

In [11…

```
# Late delivery rate by product category
category_analysis = delivered_df.groupby('product_category_name_english').agg(
    total_orders=('order_id', 'count'),
    late_orders=('delivery_status', lambda x: (x.isin(['Late', 'Super Late'])).sum())
).reset_index()

category_analysis['late_pct'] = (category_analysis['late_orders'] / category_analysis['total_orders'] * 100).round(2)

Late delivery rates across all major product categories fall within a narrow 5 point band. The worst category sits at 16.47% and the 10th worst at 11.0%. This tell us the problem is not what customers are buying. It is where they live.

Candidate's Choice: Monthly Delivery Trend Analysis

As a Creative Problem Solver, I want to include one extra feature or analysis that adds specific business value, So that I can demonstrate my ability to think beyond the basic requirements.

Feature Chosen: Monthly Late Delivery Rate Analysis

Justification:

Understanding monthly trends allows Veridi to identify when their delivery system is most likely to fail. The data shows late delivery rates spike to 23.85% in March 2018 and 16.2% in November 2017, both peak demand periods. This analysis enables Veridi to proactively adjust delivery estimates before peak seasons instead of reacting after customers are already disappointed. Without this time-based view, the geographic and sentiment findings alone would not explain why performance fluctuates so dramatically across the year.

In [11…

```
# Extract order month
delivered_df['order_month'] = pd.to_datetime(delivered_df['order_purchase_timestamp']).dt.to_period('M')

# Calculate late delivery rate per month
monthly_analysis = delivered_df.groupby('order_month').agg(
    total_orders=('order_id', 'count'),
    late_orders=('delivery_status', lambda x: (x.isin(['Late', 'Super Late'])).sum())
).reset_index()

monthly_analysis['late_pct'] = (monthly_analysis['late_orders'] / monthly_analysis['total_orders'] * 100).round(2)

monthly_analysis_filtered = monthly_analysis[monthly_analysis['total_orders'] >= 50]

print("Monthly performance summary:")
print(monthly_analysis_filtered.tail(12).to_string(index=False))
```

```
Monthly performance summary:

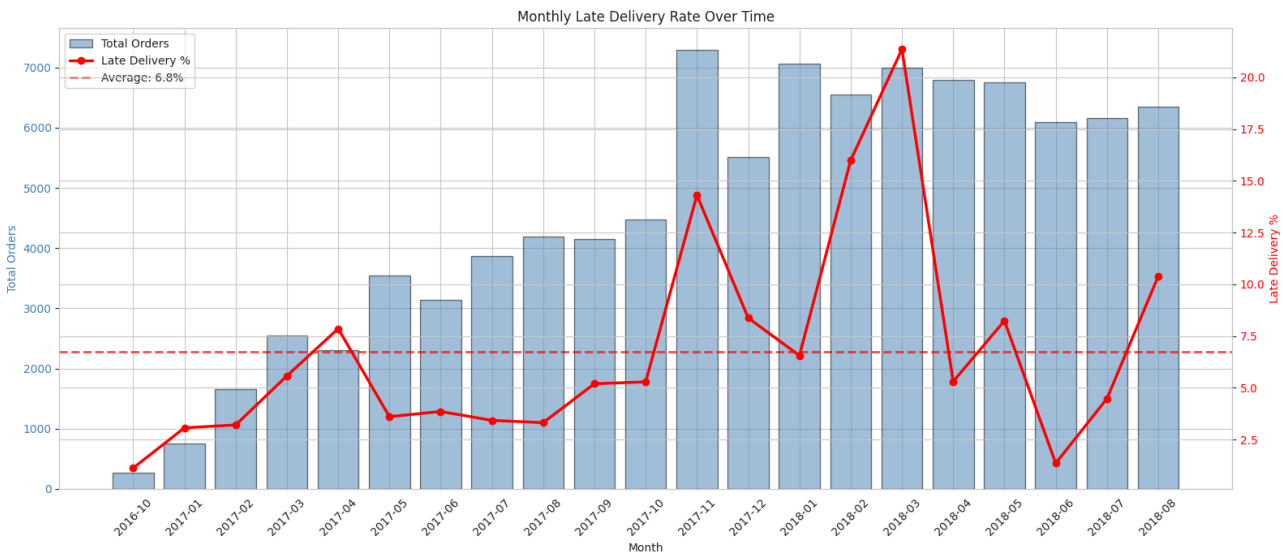
lines1, labels1 = ax1.get_legend_handles_labels()
lines2, labels2 = ax2.get_legend_handles_labels()
ax1.legend(lines1 + lines2, labels1 + labels2, loc='upper left')

plt.tight_layout()
plt.show()
```



Order volume peaked in November 2017, and late delivery rates spiked to 16.2% that same month. March 2018 reached 23.85% despite lower volumes. In quiet months the rate drops to 8%, proving the issue is seasonal capacity, not a permanent structural failure. Veridi is applying the same delivery promise year round when peak months clearly require a different approach.

In [11…

```
# Export master dataset for Streamlit dashboard
delivered_df['order_purchase_timestamp'] = pd.to_datetime(delivered_df['order_purchase_timestamp'], errors='coerce')
delivered_df['order_year_month'] = delivered_df['order_purchase_timestamp'].dt.to_period('M').astype(str)
delivered_df['is_late'] = delivered_df['delivery_status'].isin(['Late', 'Super Late']).astype(int)
delivered_df['Days_Difference'] = delivered_df['days_difference']

delivered_df.to_csv('veridi_master_dashboard_data.csv', index=False)
```

Conclusion

This audit confirms the CEO's hypothesis. Late deliveries are directly causing bad reviews, with scores dropping from 4.29 for On Time orders to 1.86 for Super Late orders. The problem is not nationwide, it is concentrated in Brazil's northeast, where Alagoas alone records a 27.2% late delivery rate. It is also seasonal, with peak months like November 2017 and March 2018 reaching rates 3 times higher than

quiet months. Product category has no meaningful impact on delivery performance.

The root causes are geographic distance from distribution centers and a one-size-fits-all delivery promise that breaks under peak demand. Three actions would directly address these findings: opening delivery centers in the northeast, adding buffer days to estimates during peak months, and setting state-level delivery deadlines instead of a single nationwide promise.
